**Common Name:** Ball Python or Royal Python  
**Scientific Name:** Python regius

**Native to:** Central and Western Africa  
**Size:** Adults average in size from three to five feet

**Life span:** Ball pythons are one of the longest-lived snakes. It is not unusual for these pythons to live 20 – 30 years in captivity. One specimen lived for 47 years at the Philadelphia Zoo.

**General appearance:** Ball pythons are named for their defense behavior of rolling into a tight ball with their head in the middle. Like all other pythons, ball pythons have spurs at their vents. There are many different color morphs and patterns available today in captive bred specimens. The “standard” ball python has large chocolate brown markings with lighter medium-brown spots interspersed between the darker spots. The belly is generally off-white or a pale gray.

**Housing requirements:**

**Enclosure:** Remember that all snakes are escape artists and when designing an enclosure it is of the utmost importance that whatever enclosure is used is made as escape-proof as possible. Generally an adult ball python should be kept in a 30-gallon sized enclosure (12 inches x 36 inches).

**Temperature:** Daytime temperatures should be maintained at 80° - 85° F

**Heat/Light:** There has been no evidence to suggest that photoperiods affect the keeping of this species. If a regular photoperiod is provided it is recommended to use fluorescent bulbs in order to minimize the extra heat generated by incandescent bulbs. When providing heat, do NOT use hot rocks. Hot rocks are notoriously unpredictable and can cause serious burn injuries to your animal. Red basking bulbs or ceramic emitters can be used to generate basking spots. Under the tank heating pads can also be used to help raise the ambient temperature of the enclosure.

**Substrate:** Newspaper and newsprint make excellent substrate even though it is not very attractive. It is easy to clean and is excellent to use when acclimating new specimens to their enclosure. Wood shavings can also be used, though cedar should never be used and some pine can also cause health problems as well. Aspen shavings are usually an excellent choice if using wood shavings. If keeping the snake on wood shavings, care should be taken when feeding the snake to avoid shavings becoming lodged in the snake’s mouth.

**Diet:** Like all snakes, ball pythons are strictly carnivorous. Adult ball pythons can be fed two to three adult mice per week. Hatchlings and juvenile animals can be fed one appropriately sized prey item per week (i.e. fuzzies for hatchlings, hoppers for slightly older animals). It is important to note here that ball pythons are notorious for not eating on a regular schedule. This is especially true of wild caught specimens. Whenever possible try to obtain captive bred snakes that have already fed to minimize problems eating. If your new ball python does not eat immediately it is important to not panic. Ball pythons have been known to go months without eating and there are records of ball pythons of not eating for 22 months. Often a variety of foods may need to be offered in order to get the snake to eat and often many will only eat live food.

**Maintenance:** Fresh water should be offered daily. If using newsprint then clean as needed. Wood shavings should be spot cleaned as needed. Periodically, the enclosure should be disinfected. A 5% bleach solution makes an excellent disinfectant. Be sure to rinse the enclosure thoroughly after disinfecting. As always, be sure to wash your hands thoroughly after handling your ball python or any cage accessories.
